Abstract
Epilepsy is a chronic disorder of the central nervous system (CNS). It affects 5-10 per 1000 of the general population. There are different types of epilepsies. For the identification of different kinds of epilepsies different test and physical examination will perform by the doctors, further to treatment of this disease the treatment involves surgery and medication. For medication of this disease many kinds of antiepileptic drugs are available which are divided into many chemical classes. Lyrica pregabalin is the new antiepileptic drug which is introduced as an antiepileptic agent in 30th December 2004 by the FDA. It is a structural derivative of the inhibitory neurotransmitter gamma amino butyric acid (GABA). Dizziness and drowsiness are the most common (>10 % patients) adverse effect of pregabalin. A hypersensitivity to pregabalin or other component of the product may develop, resulting in an unfavorable interaction with the body. Pregabalin cross the blood–brain barrier in mice, rats, and monkeys. Approximately 98 % of the radioactivity recovered in the urine was unchanged pregabalin. N-methyl is the major metabolite of pregabalin. It has been assigned to pregnancy category ‘C’ by the FDA. Pregabalin is also used off-label for the treatment of chronic pain, neuropathic pain, preoperative pain, and migraine. The maximum dosing regimen is 600 mg/day.

Keywords: Gamma amino butyric acid (GABA), hypersensitivity, dosing regimen.

INTRODUCTION
The term "epilepsy" is derived from the Greek word "epilambanein", which means "to seize upon", "to attack". Johan Jackson; who is considered as the father of modern concepts of epilepsy; nearly 1 % of the world’s populations suffer from epilepsy1. The term epilepsy refers to a disorder of brain function characterized by the periodic and unpredictable occurrence of seizures. Seizures can be “nonepileptic” when evoked in a normal brain by treatments in such as electroshock or chemical Convulsions or “epileptic” when occurring without evident provocation2. The episodic manifestations of epilepsy are dependent on the portions of the CNS involved. There are very different types of seizure, it is better to speak of epilepsies. Epilepsy is usually only diagnosed after the person has two seizures or more. The brain is responsible for all the functions of our mind and body. Seizures can happen in any part of the brain2. Epilepsy is most commonly developed in older age and an accurate diagnosis in the elderly is crucial. Elderly people have 2-3 times higher mortality than the general population4.

Figure 1: Schematic representation of different causes of epilepsy
WHO estimates that eight people per 1000 worldwide have this disease. The prevalence of epilepsy in developing countries is usually higher than in developed countries. Over half of the 50 million people with epilepsy worldwide are estimated to live in Asia. About 80% of the burden of epilepsy is in the developing world, where in some areas 80–90% of people with epilepsy receive no treatment at all. A total of about 43,704,000 people with epilepsy are reported from 108 countries covering 85.4% of the world population. Data regarding the inclusion of first-line antiepileptic drugs in the country’s list of essential drugs show that Phenobarbital is included in 95% of the responding countries, carbamazepine in 93%, phenytoin in 86%, and valproic acid in 87%. Migralepsy terminology use for “visual symptoms followed by migraine and subsequently by symptoms characteristic of epilepsy”.

Structure of the brain

![Schematic representation of different parts of human brain](image)

**Pathophysiology**

The convulsion result from sudden hyper synchronization of electrical discharge in neuronal networks in an apparently normal or a diseased cerebral cortex. The mechanisms and reasons for the discharge are not well understood. One hypothesis is that a group of diencephalic neurons normally exerts a constant inhibitory influence on cortical neurons, therapy preventing excessive discharge. In epilepsy, the neurons are differences, supersensitive and susceptible to activation or depolarization by a variety of stimuli. Seizures may result from a reduction of inhibitory neurotransmission mediated by the neurotransmitter gamma-aminobutyric acid (GABA) or by enhancement of the excitatory neurotransmitter system mediated by glutamate and aspartate. During a seizure, consciousness may be unaffected, lost completely, or altered but not completely lost. Patients may experience only minor interruptions in their motor activity or they may experience intense muscular activation that leads to motor behavior characteristic of generalized tonic-clonic seizures.

**General symptoms of epilepsy**

The symptoms of epilepsy vary from person to person. Some people may have simple staring spells, while others have violent shaking and loss of alertness. The type of seizure depends on the part of the brain affected and cause of epilepsy.

- **Seizures**
- **Convulsions**
- **Abnormal body movements**
- **Loss or disturbed consciousness**

**Type of seizure**

Seizures have been classified into two broad groups: partial (focal), and generalized.
Partial
The symptoms of each seizure type depend on the site of neuronal discharge and on the extent to which the electrical activity spreads to other neurons in the brain.

Simple partial
These seizures are caused by a group of hyperactive neurons exhibiting abnormal electrical activity, which are confined to a single locus in the brain. The electrical discharge does not spread, and the patient does not lose consciousness.

Complex partial
These seizures exhibit complex sensory hallucinations, mental distortion, and loss of consciousness. Motor dysfunction may involve chewing movements, diarrhea, or urination. Eighty percent of individuals with complex partial epilepsy experience their initial seizures before twenty years of age.

Generalized
These seizures begin locally, but they rapidly spread, producing abnormal electrical discharges throughout both hemispheres of the brain. Generalized seizures may be convulsive or non convulsive, and the patient usually has an immediate loss of consciousness.

Tonic-clonic (grand mal)
This is most commonly encountered- and the most dramatic- form of epilepsy. Seizures result in loss of consciousness, followed by tonic (continuous contraction) and then clonic (rapid contraction and relaxation) phases. The seizure is followed by a period of confusion and exhaustion due to the depletion of energy stores.

Absence (petit mal)
These seizures involve a brief, abrupt, and self-limiting loss of consciousness. The onset occurs in patients at three to five years of age and lasts until puberty. The patient stares and exhibits rapid eye-blinking, which lasts for three to five seconds.

Myoclonic
These seizures consist of short episodes of muscle contractions that may reoccur for several minutes. Myoclonic seizures are rare, occur at any age, and are often a result of hypoxia, uremia, encephalitis, or drug poisoning.

Febrile seizures
Young children (3 months to 5 years of age) frequently develop seizures with illness accompanied by high fever. The febrile seizures consist of generalized tonic clonic convulsions of short duration. Although febrile seizures may be frightening to observers, they are benign and do not cause death, neurologic damage, injury, or learning disorders, febrile seizures require medication.

Status epilepticus
These seizures are rapidly recurrent.
Table 1: Different classes of seizures with their causes and symptoms

<table>
<thead>
<tr>
<th>Types of seizure</th>
<th>Absence (petit mal) seizure</th>
<th>Generalized tonic-clonic (grand mal) seizure</th>
<th>Partial (focal) seizure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Causes</td>
<td>Occur most often in people under age 20, usually in children ages 6 to 12. They may occur with other types of seizures, such as generalized tonic-clonic seizures (grand mal seizures), twitches or jerks (myoclonus), or sudden loss of muscle strength (atonic seizures).</td>
<td>It may occur in people of any age. They may occur once (single episode) or as part of a repeated, chronic condition (epilepsy).</td>
<td>By abnormal electrical disturbances in the brain.</td>
</tr>
<tr>
<td>Symptoms</td>
<td>Occur many times a day. Occur for weeks to months before being noticed. Be mistaken for lack of attention or other misbehavior. During the seizure, the person may: Stop walking and start again a few seconds later. The person usually does not fall during the seizure.</td>
<td>Biting the cheek or tongue. Clenched teeth or jaw. Loss of urine or stool control (incontinence). Stopped breathing or difficulty breathing. Blue skin color. After the seizure, the person may have: Normal breathing. Sleepiness that lasts for 1 hour or longer. Loss of memory (amnesia) regarding events surrounding the seizure episode.</td>
<td>Abnormal muscle contraction. Lip smacking. Chewing/swallowing without cause. Forced turning of the eyes. Nausea. Sweating. Flushed face. Dilated pupils. Rapid heart rate/pulse. Blackout spells periods of time lost from memory.</td>
</tr>
</tbody>
</table>

Examination and Tests
The doctor will perform a physical examination, which will include a detailed look at the brain and nervous system. An EEG (electroencephalogram) will be done to check the electrical activity in the brain. The brain may appear normal after a seizure or between seizures. Up to 5% people without epilepsy may have nonspecific abnormalities in their EEG recording; while up to 40% of people with epilepsy may have a normal EEG recording between seizures.

Tests that may be done include:
- Blood chemistry
- Blood sugar
- CBC (complete blood count)
- Kidney function tests
- Liver function tests
- Lumbar puncture (spinal tap)
- Tests for infectious diseases
Figure 5: Electroencephalography (EEG) recording of different seizure in human brain

**Treatment**

**Medication**

To prevent seizures, called anticonvulsants, may reduce the number of future seizures. These drugs are taken by oral route. These are prescribed depending on the type of seizures. Many epilepsy medications cause birth defects. Women wishing to become pregnant should tell the doctor in advance in order to adjust medications. Epilepsy that does not get better after two or three anti-seizure drugs have been tried is called "medically refractory epilepsy". Bromide (1857) was the first drug to be used for the treatment of epilepsy, but it is now obsolete.

**Surgery**

If epilepsy seizures are due to a tumor, abnormal blood vessels, or bleeding in the brain, surgery to treat these disorders may make the seizures stop. Epilepsy surgery is available in 40.9% of the responding countries.**

MODERN TREATMENT OF EPILEPSY
LYRICA (PREGABALIN)
LYRICA APPROVAL HISTORY
FDA approved: First approved December 30th, 2004
Brand name: Lyrica
Generic name: Pregabalin
Company: Pfizer Inc.
Treatment for:
- Neuropathic pain
- Post herpetic neuralgia
- Fibromyalgia
- Diabetic peripheral neuropathy
- Epilepsy

Lyrica (pregabalin) is a modulator of voltage-gated calcium channels, designed to affect neurological transmission in multiple systems. Lyrica is specifically indicated for the treatment of neuropathic pain associated with diabetic peripheral neuropathy, post herpetic neuralgia, and spinal cord injury; as an adjunctive therapy for partial onset seizures and for the treatment of fibromyalgia.

Clinical Results of Lyrica (Pregabalin)
Lyrica (pregabalin) is a structural derivative of the inhibitory neurotransmitter gamma amino butyric acid indicated for the management of neuropathic pain associated with diabetic peripheral neuropathy, post herpetic neuralgia and spinal cord injury; as an adjunctive therapy for partial onset seizures and for the treatment of fibromyalgia.

Chemical structure

Solubility: Freely soluble in water and both acidic and basic solution

Half life: 6.3 hours

Dose size: 25 – 300 mg

Dosage forms: Solid, liquid (20 mg/ml)

Pharmacology

Pregabalin is a structural derivative of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA); however, it does not directly bind to GABA receptors. Pregabalin binds to the alpha2-delta site of voltage-gated calcium channels in the central nervous system (CNS) tissues. This calcium channel modulation may reduce the release of many neurotransmitters. Like gabapentin, the precise mechanism of action of Pregabalin is unknown. Gabapentin differs from Pregabalin because of the reduced binding affinity to voltage-gated calcium channels. Pregabalin is six-times more potent than gabapentin in binding affinity to the alpha2-delta voltage-gated calcium channel. The manufacturer states that 50 mg of Pregabalin is approximately equal to 300 mg of gabapentin. This alteration of calcium channel function is not to be confused with calcium-channel blockers. Pregabalin and gabapentin alter channel function without complete blockade of the calcium channel resulting in virtually no change in systemic blood pressure or coronary blood flow changes.

Mechanism of action (MOA) of Lyrica (In diagram)

Lyrica is thought to rebalance neurotransmitters involved in central pain amplification.

Figure 6: Schematic representation of MOA of Lyrica
Drug Interactions

Excretion

Metabolism

Distribution

Adverse effects

Over dosage

Several renal failure patients developed myoclonus while receiving pregabalin, apparently as a result of gradual accumulation of the drug. Acute over dosage may be manifested by somnolence, tachycardia and hypertonicity. Plasma, serum or blood concentrations of pregabalin may be measured to monitor therapy or to confirm a diagnosis of poisoning in hospitalized patients.

Pharmacokinetics

Absorption

Pregabalin oral bioavailability is estimated to be greater than or equal to 90% and is independent of dose. The rate of pregabalin absorption is decreased when given with food resulting in a decrease in $C_{max}$ by approximately 25 to 30% and a delay in $t_{max}$ of approximately 2.5 hours. Administration with food, however, has no clinically significant effect on the extent of absorption\(^\text{20}\).

Distribution

Pregabalin cross the blood–brain barrier in mice, rats, and monkeys. It has been shown to cross the placenta in rats and is present in the milk of lactating rats. In humans, the volume of distribution of pregabalin for an orally administered dose is approximately 0.56 L/kg and is not bound to plasma proteins.

Metabolism

Approximately 98% of the radioactivity recovered in the urine was unchanged pregabalin. The major metabolite is N-methyl pregabalin.

Excretion

Pregabalin is eliminated from the systemic circulation primarily by renal excretion as unchanged drug. Renal clearance of pregabalin is 73 ml/minute.

Drug Interactions

The manufacturer notes some potential pharmacological interactions with opioids (pregabalin is synergistic with opioids in lower doses), benzodiazepines, barbiturates, ethanol (drinking alcohol), and other drugs that depress the central nervous system. A hypersensitivity to pregabalin or other component of the product may develop, resulting in an unfavorable interaction with the body\(^\text{20}\).

Adverse drug reactions associated with the use of Pregabalin

<table>
<thead>
<tr>
<th>Condition</th>
<th>Adverse effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very common (&lt;10% of patients)</td>
<td>Dizziness, drowsiness.</td>
</tr>
<tr>
<td>Common (1-10% of patients)</td>
<td>Blurred vision, diplopia, increased appetite, euphoria, confusion, vivid dreams, changes in libido (increase or decrease), irritability, ataxia, attention changes, abnormal coordination, memory impairment, tremors, dysarthria, paresthesia, vertigo, dry mouth and constipation, vomiting and flatulence, erectile dysfunction, fatigue, peripheral edema, drunkenness, abnormal walking, weight gain, asthenia, nasopharyngitis, increased creatine kinase level. Depression, lethargy, agitation, anorgasmia, hallucinations, myoclonus, hypoesthesia, hyperesthesia, tachycardia, excessive salivation, sweating, flushing, rash, muscle cramp, myalgia, arthralgia, urinary incontinence, dysuria, thrombocytopenia, kidney calculi. Neutropenia, first degree heart block, hypotension, hypertension, pancreatitis, dysphagia, oliguria, rhabdomyolysis, suicidal thoughts or behavior.</td>
</tr>
<tr>
<td>Infrequent (0.1-1% of patients)</td>
<td></td>
</tr>
<tr>
<td>Rare (&lt;0.1% of patients)</td>
<td></td>
</tr>
</tbody>
</table>

Note: Pregabalin may also cause withdrawal effects after long-term use if discontinued abruptly.

Pregnancy

Pregabalin has been assigned to pregnancy category ‘C’ by the FDA. Animal studies have revealed increased incidences of fetal structural abnormalities and other manifestations of developmental toxicity including lethality, growth retardation and both nervous and reproductive system functional impairment. Animal studies have reported that pregabalin crosses the placenta and have shown an increased risk in male-mediated teratogenicity. There are no controlled data in human pregnancy. Pregabalin should only be given during pregnancy when there are no alternatives and benefit outweighs risk.

Major seizures- major seizures are harmful to the developing fetus because of the possibility of anoxia and metabolic disorder.

Minor seizures- Minor seizures are probably harmless and therefore need not be eradicated.

Breast feeding

While taking pregabalin may cause risk to the infant because the drug has been shown to be excreted in the breast milk of rats. Human studies are unknown, but the use of pregabalin while breast feeding is not recommended. Anti-epilepsy drugs pass into breast milk, Phenobarbital, primidone and ethosuximide in significant quantities, phenytoin and sodium valproate less so\(^\text{12}\).

High risk group

The drug should not be given to pregnant mothers, cardiac / hypertensive patients, patients suffering from kidney dysfunction and geriatrics.

Warnings and precautions

Do not drink alcohol while taking pregabalin. Alcohol can add to the drowsiness caused by this medication. The Doctor should be informed if the patient is allergic to pregabalin. Caution should be exercised when prescribing pregabalin to patients who have had a previous episode of angioedema.

Figure 7: LYRICA 75 mg capsules the brand of Pfizer
Uses
Pregabalin is also used off-label for the treatment of chronic pain, neuropathic pain, preoperative pain, and migraine. Usually physicians will start the patient on a low dose of pregabalin and increase it gradually, depending on the patient's evaluation. Its therapeutic effect appears after 1 week of use and is similar in effectiveness to lorazepam, alprazolam and venlafaxine but pregabalin has demonstrated superiority by producing more consistent therapeutic effects of psychic and somatic anxiety symptoms. Long-term trials have shown the continued effectiveness without the development of tolerance and additionally unlike benzodiazepines it does not disrupt sleep architecture and produces less severe cognitive and psychomotor impairment; it also has a low potential for abuse and dependence and may be preferred over the benzodiazepines for these reasons. There is not enough data to state that it should be used in all neuropathic pain, and it has not been found to be effective for HIV-associated peripheral neuropathy.18,19

Storage conditions of Pregabalin
Capsules: Store in a well closed container, between 15°-30°C. Protect from moisture and heat.19

CONCLUSION
Lyrica (Pregabalin) is specifically indicated for the treatment of neuropathic pain associated with spinal cord injury. It is also indicated for the treatment of neuropathic pain associated with diabetic peripheral neuropathy, for post herpetic neuralgia, for fibromyalgia, and as an adjunctive therapy for adults with partial onset seizures. Lyrica is supplied as a hard-gelatine capsule for oral administration. The recommended initial dose of the drug for the treatment of neuropathic pain associated with spinal cord injury is 150 mg/day (75 mg twice/day), which can be escalated to 300 mg/day within the first week. The maximum dosing regimen is 600 mg/day.
